

The Spanish Households' Carbon Footprint Inequality in High Definition & Real Time

Barrutiabengoa, J. (BBVA Research), Carvalho (Cambridge & CEPR),
Cubero, J (BBVA Research) ,Hansen, S.(UCL & CEPR), Ortiz,
A. (BBVA Research), Rodrigo, T (BBVA Research)
and Rodriguez-Mora, J (Edinburg & CEPR)

Key Messages

- We present the Environmental Distributional Accounts for GHG Emissions of Spanish Households combining Input-Output methodology with a novel rich Big Data database.
- There is a high inequality in CO₂ emissions, in line with consumption but lower than income. Carbon footprint Inequality is highly connected to the use of transport.
- The Co₂ emissions from Housing and Energy utilities are more balanced, with relatively higher consumption in the lower percentiles of consumption.
- The Big Data properties enables the design of Smart Policies or those addressed where more needed and/or more effective.
- Our approach also enables the estimation of Household's emissions in real time. The data shows important divergences during Covid-19 by emissions and gases.

Our approach: Input-Output analysis, official data & Big Data

- **Macro Consistency:** We rely on the standard Macro I-O Approach and on a macro Consistent “Consumption Based” CO2 emissions.
- **Direct & Indirect Emissions:**
 - “Direct Emissions”: Directly emitted by individuals. Emissions originated from the use of private vehicles or physical combustion at home (i.e.: natural gas for heating).
 - “Indirect Emissions”: emissions embedded in the consumption of goods and services, including energy utilities without physical combustion at home (i.e.: electricity).
- **Distributional accounts and Real Time GHG Emissions:** By Linking CO2 and CH4 by category (COICOP) to our Distributional Accounts of Consumption.

Taking official direct emissions data and adding the estimation of indirect ones (70% of total emissions) by category of consumption

CO2 Emissions In High Definition: The potential for Smart Policies

Distribution of CO2 Emissions: Important role of Transport and Energy Utilities but in the opposite tails of the consumer distribution

SPAIN: CO2 EMISSIONS 2021: LEVELS AND SHARE (%)

(CO2 EMISSIONS BY CONSUMPTION CATEGORIES AND PERCENTILES OF CONSUMPTION)

CO2 Emissions Inequality is high in line with consumption but lower than income

The top 10% percentile of consumers account for 25% of Co2 Emissions...

...and emit 8.5X times more Co2 than the bottom 10%...

...The top 10% generates 16.5X more emissions in transport than the bottom 10%...

...The top 1% consumers emit 30.X times more than the bottom 10%

Are all Gases Alike?: Not Really

SPAIN: METHANE EMISSIONS 2021: LEVELS AND SHARE (%)

(CH₄ MISSIONS BY CONSUMPTION CATEGORIES AND PERCENTILES OF CONSUMPTION)

02

Conclusions

Conclusions

- The combination of Input-Output Models and Big Data allows us to analyze the Sustainability of Households in high detail.
- We estimate Indirect emissions (70% of total) in real time time and high definition, while we take the direct ones consistent with official data.
- High inequality exists in CO2 emissions resulting from our income, preferences, lifestyles ... affecting our consumption.
- The inequality is mainly the result of the CO2 emissions by transport which are concentrated in the highest consumption percentiles and younger people.
- The role of Energy Utilities is different: an important (but less than transport) source of emissions that is more relevant for low consumers and older people.
- The Distributional accounts and Real time components of this approach open the door for the design of Smart Policies to better fight climate change.
